Abstract

Time series data from scientific fields as diverse as astrophysics, economics, human 14 movement science, and neuroscience all exhibit fractal properties. That is, these time series 15 often exhibit self-similarity and long-range correlations. This fractalRegression package 16 implements a number of univariate and bivariate time series tools appropriate for analyzing 17 noisy data exhibiting these properties. These methods, especially the bivariate tools 18 (Kristoufek, 2015a; Likens, Amazeen, West, & Gibbons, 2019) have yet to be implemented 19 in an open source and complete package for the R Statistical Software environment. As both practitioners and developers of these methods, we expect these tools will be of interest to a wide audience of scientists who use R, especially those from fields such as the human movement, cognitive, and other behavioral sciences. The algorithms have been developed in C++ using the popular Rcpp (Eddelbuettel & Francois, 2011) and RcppArmadillo (Eddelbuettel & Sanderson, 2014) packages. The result is a collection of 25 efficient functions that perform well even on long time series (e.g., $\geq 10,000$ data points). 26 In this work, we motivate introduce the package, each of the functions, and give examples 27 of their use as well as issues to consider to correctly use these methods. 28

52

fractalRegression: An R package for multiscale regression and fractal analyses

32 Introduction

Fractal analysis, in its many forms, has become an important framework in virtually 33 every area of science, often serving as an indicator of system health (Goldberger et al., 34 2002), adaptability (Bak, Tang, & Wiesenfeld, 1987), control (Likens, Fine, Amazeen, & 35 Amazeen, 2015), cognitive function (Euler, Wiltshire, Niermeyer, & Butner, 2016), and 36 multi-scale interactions (Kelty-Stephen, 2017). In particular, various methods related to 37 Detrended Fluctuation Analysis (DFA) (Peng et al., 1994) have rose to prominence due to their ease of understanding and broad applicability to stationary and nonstationary time series, alike. 40 The basic DFA algorithm has been implemented in numerous packages and software 41 programs. However, advanced methods such as Multifractal Detrended Fluctuation 42 Analysis (MFDFA) (Kantelhardt et al., 2002), Detrended Cross Correlation (DCCA) (Podobnik & Stanley, 2008; Zebende, 2011), and, in particular, fractal regression techniques such as Multiscale Regression Analysis (MRA) (Kristoufek, 2015a; Likens, Amazeen, West,

& Gibbons, 2019) have not yet been implemented in a comprehensive CRAN Package for

the R Statistical Software Environment. Thus, there is a clear need for a package that

incorporates this functionality in order to advance theoretical research focused on

49 understanding the time varying properties of natural phenomena and applied research that

uses those insights in important areas such as healthcare (Cavanaugh, Kelty-Stephen, &

Stergiou, 2017) and education (Snow, Likens, Allen, & McNamara, 2016).

Package Overview

Some foundational efforts in fractal analyses, which partially overlap with the functionality of this package, have been implemented elsewhere. For example, a number of univariate fractal and multifractal analyses have been implemented in the 'fracLab' library for MATLAB (Legrand & Véhel, 2003) and other toolboxes that are mainly targeted at multifractal analysis (Ihlen, 2012; Ihlen & Vereijken, 2010). In terms of open access packages, there are other packages that implement some, but not all of the same functions such as the fathon package (Bianchi, 2020) that has been implemented in Python as well as the R packages: fractal [@], nonlinearTseries (Garcia, 2020), and MFDFA (Laib, Golay, Telesca, & Kanevski, 2018). However, none of the above packages incorporate univariate monofractal and multifractal DFA with bivariate DCCA and MRA nor do they run on a C++ architecture. Our fractalRegression package is unique in this combination of analyses and efficiency. For instance, we are not aware of any other packages that feature MRA and Multiscale Lagged Regression (MLRA).

Methodological Details and Examples

In order to demonstrate the methods within the 'fractalRegression' package, we group this into univariate (DFA, MFDFA) and bivariate methods (DCCA, MRA, MRLA). For each method, we 1) highlight the key question(s) that can be answered with that method, 2) briefly describe the algorithm with sources for additional details, 3) describe some key consideration for appropriately applying the algorithm, and demonstrate the use of the functions on a 4) simulated and 5) empirical application of the function.

Table 1. Overview of package functions, objectives, and output.

74 Univariate Methods

66

73

Detrended Fluctuation Analysis. The key question that can be answered by

Detrended Fluctuation Analysis (DFA) (Peng et al., 1994) is: what is the magnitude and

direction of long range correlation in a single time series? While DFA has been described

extensively elsewhere (Kantelhardt, Koscielny-Bunde, Rego, Havlin, & Bunde, 2001) and

visualized nicely (Kelty-Stephen, Stirling, & Lipsitz, 2016), we provide a brief summary

- here. DFA entails splitting a time series into several small bins (e.g., 16). In each bin, the least squares regression is fit and subtracted within each window. Residuals are squared and averaged within each window. Then, the square root is taken of the average squared residual across all windows of a given size. This process repeats for larger window sizes, growing by, say a power of 2, up to N/4, where N is the length of the series. In a final step, the logarithm of those scaled root mean squared residuals (i.e., fluctuations) is regressed on the logarithm of window sizes. The slope of this line is termed α and it provides a measure of the long range correlation. Conventional interpretation of α is: $\alpha < 0.5$ is anti-correlated, $\alpha = 0.5$ is uncorrelated, white noise, $\alpha > 0.5$ is temporally correlated, $\alpha = 1$ is long-range correlated, 1/f-noise, pink noise, $\alpha > 1$ is non-stationary and unbounded, and $\alpha = 1.5$ is fractional brownian motion.
- 91 DFA Examples.
- To demonstrate the use of dfa() we simulate three time series using the fgn_sim function. In particular, we simulate white noise, pink noise, and anti-correlated fractional Gaussian noise.

```
# Generate pink noise
set.seed(34534534)
pink.noise <- fgn_sim(n = 5000, H = 0.9)</pre>
```

Then we can run DFA on these using the example code below.

Multifractal Detrended Fluctuation Analysis. Multifractal Detrended
Fluctuation Analysis (MFDFA; Kantelhardt et al. (2002)) is an extension of DFA by

101

102

generalizing the fluctuation function to a range of exponents of the qth order. The key
question that can be answered by MFDFA is: how does the magnitude and direction of long
range correlation change over time within a single time series?

MFDFA Examples. INCLUDE EXAMPLES HERE

DFA and MFDFA Considerations.

We recommend a few points of consideration here in using this function. One is to be sure to verify there are not cross-over points in the logScale-logFluctuation plots (Peng et al., 1994; Perakakis, Taylor, Martinez-Nieto, Revithi, & Vila, 2009). Cross-over points (or a visible change in the slope as a function of of scale) indicate that a mono-fractal characterization does not sufficiently characterize the data. If cross-over points are evident, we recommend proceeding to using the 'mfdfa()' to estimate the multi-fractal fluctuation dynamics across scales.

While it is common to use only linear detrending with DFA, it is important to inspect the trends in the data to determine if it would be more appropriate to use a higher order polynomial for detrending, and/or compare the DFA output for different polynomial orders (Kantelhardt, Koscielny-Bunde, Rego, Havlin, & Bunde, 2001).

General recommendations for choosing the min and max scale are an sc_min = 10
and sc_max = (N/4), where N is the number of observations. See Eke et al. (2002) (Eke,
Herman, Kocsis, & Kozak, 2002) and Gulich and Zunino (2014) (Gulich & Zunino, 2014)
for additional considerations. - Key Question and method description. - Simulated data:
fGN - Empirical data: EPICLE Movement Data? - MFDFA - Key Question(s) - Simulated
data: mfbrownian motion from Ihlen matlab (Aaron might have R port) see mbm_mgn for
R from aaron - Empirical data: EPICLE Movement Data?

Bivariate Methods

Detrended Cross-Correlation Analysis. Detrended Cross-Correlation Analysis

(DCCA; CITE) is a bivariate extension of the DFA algorithm. The key questions that can

be asked it are: a) How does correlation between two time series change as a function of

scale? and b) What is/are the dominant (time) scale(s) of coordination? (those that are

beyond a threshold, or statistically significant given a criteria, or of a certain magnitude?

DCCA Examples.

- Simulated data: MC-ARFIMA
- Empirical data: EPICLE Movement Data?

Multi-scale Regression Analysis. Multi-scale regression analysis (MRA) is an adaptation of DCCA that brings the analyses into a predictive framework Kristoufek (2015b). The key questions that can be answered by it are: a) How does the influence of one time series on another time series change as a function of scale? and b) What is/are the dominant (time) scale(s) of influence of one time series on another time series?

MRA Examples.

MRA

- Simulated data:
 - Empirical data: FNIRS from Aaron?

Multi-scale Lagged Regression Analysis. Multi-scale lagged regression analysis
is an extension of MRA that allows for examining the influence as a function of scale, but
also of time lag. In parituclar, the key questions that can be asked with MLRA are: a)
How does the influence of one time series on another time series change as a function of
scale at different time lags? and b) Does the dominant time scale of influence change over
successive time lags?

$MLRA\ Examples.$

Surrogate Methods (and 'full' data analysis)

Methods are ranked in terms of increasing levels of rigor.

- Randomization Estimates should be different.
- IAAFT Estimates should be different.
- Model based surrogate (Simulated exponents) See Likens 2019 paper with model of
 postural sway/control, taking an educated guess about the data generating process
 underlying the time series. Estimates should not be different. See Roume et al 2018
 windowed detrended CCA
 - Can we incorporate lags into MC-ARFIMA?

General Discussion

- General value of methods and the types of questions
- Practical consideration of univariate methods
- Practical consideration of bivariate methods
- Unique contribution of the methods
